CHAPTER 5
PROJECT

Web Programming with HTML5, CSS, and JavaScript/First Edition
John Dean

Implement a web page that displays an invoice form as shown in the screenshot below.

Use a `table` element with other appropriate table-oriented elements. Although the rows and columns are more for layout than for holding data, the spanned cells mean that the implementation will be more straightforward if you use the `table` element rather than the CSS `display` property with table values.

Specify the four columns' widths using percentages: 40% for Product Name, 25% for Color, 15% for Quantity, and 20% for Price.

Use a nonzero value for padding around cell text.
